

Binding in a complex aggregate structure

A binding connector connecting deep nested properties in a block must apply a stereotype «NestedConnectorEnd» at both ends and specify the propertyPath (see [Nested Connector end](#) for more information about the nested connector end). If there are multiple values specify a property in the propertyPath (the upper bound of the multiplicity of the property is greater than 1 or is infinite), Magic Model Analyst will construct a value list at each end of the connector and maintain the values in the list. You can use (IsOrdered = true) to order each property in the propertyPath to ensure that the order of values on the list remains the same.

The following figure illustrates an example of binding where the aggregate structure is complex. It shows an executable InstanceSpecification of the block **System**, which is **system:System**. It has three instances of subsystems as the values of the slot **subsystem:Subsystem[0..*]**. In the SysML Parametric diagram, the value property ***value** of the slot **subsystem:Subsystem[0..*]** are bound to the value property **value** of the block **System**. So, the values of the value property **value** of object **System** will be [25, 50, 75] respectively.

Value Binding in a Complex Aggregation Structure.
