How synchronization works

DataHub synchronization capability is a core feature of the DataHub. Synchronization is primarily used for keeping track of changes. This synchronization feature allows you to track different types of node changes, to update or remove DHLinks from the **Synchronize** button on either side of the MagicDraw Containment area or DataHub Explorer, to synchronize Data Sources with other collaboration tools, and to choose to synchronize single, grouped, or entire Data Source.

The following videos show the data synchronization and the data links in action:
