

Getting a tag value

You can use the following API to get a tag value:

```
public Object getTagValue(Object_ object, String tagName) throws Exception {  
    ...  
}
```

If the `RuntimeObject` is omitted, **\$context\$** or **self** will be used as an object. The context object in the parametric is the constraint block object that owns the constraint, not the actual context of the diagram. The following example shows how to get a tag value without specifying a `RuntimeObject` in ALH API:

```
public Object getTagValue(String tagName) throws Exception {  
    ...  
}
```

The following code fragment shows how to get tag values, e.g., *max*, through ALH API. See also [Value access and references by tags](#).

```
ALH.getTagValue(d, "uniform.max");           // 10
```
