

Specifying parameters

The number of parameters a script operation can have depends on the script operation language:

- An OCL expression can have a single parameter, which by default specifies the [Contextual element](#). Though the parameter cannot be removed, you can easily reset the [Contextual element](#), if necessary.
- A binary expression inherits parameters from the Java class to which the expression body references. You cannot create additional parameters.
- Other script operations, such as JavaScript or Groovy, can have as many parameters as you need (see the following figure).
