Subproperty

A subproperty is a more specific kind of property than some other property, and a super property is a more general kind of property than some other property. For example, "has father" is a more specific property than "has parent", and "has parent" is a more general property than either "has mother" or "has father". In the concept modeling interpretation of UML, subsetting a property creates a subproperty when the subsetting property has a different name than the subsetted property. (See section 3.5 Existential Quantification Constraint, for when the name is the same or is omitted.) UML provides a {subsets} constraint that asserts that the values within a subsetting property are also in the set of values within a subsetted property. To stay as close to standard UML as possible, the concept modeling profile interprets a subsetting property having a different name as a subproperty.

The diagram below shows that the property "is capacity of" (owned by the class "Legal Capacity") is a subset of the global property "is conferred on" (from the property holder "Thing").

Note Property, the subsetting property must have a different name than the property it subsets.

```
Autonomous Agent is capacity of has capacity (Agents)

1..*

* (Legal Capacities)

{subsets is conferred on}
```

```
«PropertyHolder»
Thing
(Relations)

**attributes*

+has member : Thing [*]
+provides : Thing [*]
+is conferred on : Thing [*]
+has responsibility : Duty [*]
+is conferred by : Thing [*]

**is mandated by : Thing [*]{subsets is conferred by}
```

Property 'is conferred on' and subproperty 'is capacity of' having different names.
