

Alf Tutorial 3: Stopwatch

This tutorial you will construct a state machine model for a simple stopwatch that increments by 1 every second. This model is a version of the stopwatch model used in the [tutorial for Magic Model Analyst \(MSI\)](#). However, unlike in the MSI toolkit, Behaviors will be defined using Alf, rather than Activity diagrams.

The stopwatch structure

The structure of the stopwatch model in this tutorial is very simple. It only contains a *time* property, which is typed as *Integer*. The *time* property records the elapsed time once the stopwatch receives a starting Signal. Therefore, the structure of the stopwatch system contains a *StopWatch* class that has the *time* property.

The stopwatch behavior

The tutorial uses a State Machine diagram to describe the main behavior of the stopwatch. The State Machine consists of four States:

1. *ready* – The State in which the stopwatch is ready to start.
2. *running* – The State that the stopwatch enters once it receives a *Start* signal. The stopwatch runs and the timer starts. The stopwatch is triggered by a Time Event to increment the *time* value by 1 each second.
3. *paused* – The State in which the stopwatch is paused and waiting for the user to restart it.
4. *stopped* – The State in which the stopwatch stops running.

The tutorial consists of the following steps:

- [Creating the StopWatch structure](#)
- [Creating the StopWatch state machine](#)
- [Defining the Stopwatch operations using Alf](#)
- [Defining the Ready and Running behaviors using Alf](#)
- [Running the Stopwatch model](#)
